II. Discussion

As directed in SRM-SECY-11-0089, “Options for Proceeding with Future Level 3 Probabilistic Risk Assessment (PRA) Activities,” the staff is conducting a full-scope multi-unit site Level 3 PRA (Level 3 PRA project) that addresses all internal and external hazards, all plant operating modes, and all reactor units, spent fuel pools (SFPs), and dry cask storage. The reference site for this study contains 2 four-loop Westinghouse pressurized water reactors with large dry containments. The objectives of the Level 3 PRA project are to (1) develop a Level 3 PRA, generally based on current state-of-practice methods, tools, and data, that (a) reflects technical advances since the last NRC-sponsored Level 3 PRAs (NUREG-1150), which were completed over 30 years ago, and (b) addresses

scope considerations that were not previously considered (e.g., low-power and shutdown risk, multi-unit risk, other radiological sources); (2) extract new insights to enhance regulatory decision making and to help focus limited NRC resources on issues most directly related to the agency’s mission to protect public health and safety; (3) enhance PRA staff capability and expertise and improve documentation practices to make PRA information more accessible, retrievable, and understandable; and (4) demonstrate technical feasibility and evaluate the realistic cost of developing new Level 3 PRAs.

The work performed under this project is being documented as a multi-volume report. The current Level 3 PRA project reports describe the analyses and results for the SFP combined Level 1 and Level 2 PRA for all hazards (Volume 6a) and the SFP Level 3 PRA for all hazards (Volume 6b). Consistent with previous SFP studies, seismic events were found to be the dominant contributors (particularly, the higher

seismic bins). However, effectively no populations were projected to receive the high doses needed to result in early health effects. The bulk of the radiological exposure (which is in the low to very low dose range) arises from reoccupation of land after decontamination and natural decay and weathering reduce exposures to levels below the habitability criteria assumed in the analysis. The study also found that the risk (which considers both frequency and consequences) of latent fatality for the SFPs is less than that for the reactors.

While these results can vary for other plants due to variations in their design and siting, the estimates derived for the reference plant, when adjusted for siting and design variations, would provide useful qualitative risk insights for other U.S. operating plants.
